1 Background and methodology

Mott MacDonald has been commissioned by Surrey Downs, Sutton and Merton CCGs to undertake an initial equalities analysis (EA). This work will support local commissioners to understand which protected characteristic groups may be affected by any changes to the delivery of acute services. The following chapter will outline the context for this analysis and the approach undertaken by Mott MacDonald.

1.1 Improving Healthcare Together 2020-2030

The Improving Healthcare Together 2020-2030 programme, led by NHS Surrey Downs, Sutton and Merton Clinical Commissioning Groups (CCGs), is working to improve healthcare sustainably. It is working to address three main challenges in the combined geography of the three CCG areas. These are:

- Improving clinical quality
- Providing healthcare from modern buildings
- Achieving financial sustainability

The Improving Healthcare Together issues paper states that six major acute services¹ may need to change so that people who are very unwell, or at risk of becoming very unwell, get the right support straight away from senior specialist staff.

Three potential solutions have been put forward:

- Locating **major acute services at Epsom Hospital**, and continuing to provide all district services at both Epsom and St. Helier
- Locating **major acute services at St. Helier Hospital**, and continuing to provide all district hospital services at both Epsom and St. Helier
- Locating **major acute services at Sutton Hospital**, and continuing to provide all district services at both Epsom and St. Helier²

1.2 Equality analysis and scope of this report

It is important that those involved in making decisions about future health service configuration understand the full range of potential impacts that any changes could have on the local population. It is particularly important that they understand the potential impact on groups and communities who will be the most sensitive to service changes.

Within this context, this initial EA will help local NHS commissioners to understand which groups, particularly protected characteristic groups, are likely to have a greater need for acute services and are therefore more likely to be impacted by any changes in provision. This report focuses on the following acute services:

- A&E
- Acute medicine
- Emergency general surgery

¹ A&E, acute medicine, emergency general surgery, intensive care, obstetrics, paediatrics

² Improving Healthcare Together 2020-2030: NHS Surrey Downs, Sutton and Merton Clinical Commissioning Groups Issues Paper accessed online at <http://www.surreydownsccg.nhs.uk/media/271539/committee-in-common-papers-combined.pdf>

- Obstetrics
- Paediatrics

Intensive care has not been explored in its own right as admission to this unit is via admissions through emergency or elective medical and surgical services and so disproportionate need for this service will be covered in the discussion of other acute services.

As this is an initial analysis, this report is a **high-level scoping** report. It outlines preliminary observations on which groups are considered to have a disproportionate or differential need for the hospital services under review.

1.3 Methodology

The report considers each of the nine 'protected characteristic' groups as defined by the Equality Act 2010, as well as considering deprived communities and carers³. The following groups have therefore been considered in this report:

- Age – specifically children (those aged 16 and under), young people (those aged 16-24) and older people (those aged 65 and over)
- Disability
- Gender reassignment
- Marriage and civil partnership
- Pregnancy and maternity
- Race and ethnicity (Black, Asian and Minority Ethnicity (BAME), White British, White other)
- Religion and belief
- Sex
- Sexual orientation
- Carers
- Deprivation

For each group, a summary table is presented identifying whether, and for which acute services under consideration⁴, they have a disproportionate or differential need.

Definition of terms

- **Disproportionate need** refers to a need for the service/treatment over and above the general population.
- **Disproportionate use** refers to the higher use of services/treatments over and above the general population
- **Differential need** refers to a group that has different types of need for the service during delivery.

³ Although not identified as protected characteristics in equality legislation, it is accepted best practice to include those from deprived communities and carers.

⁴ Please note that this study explores the following acute service provisions: A&E, acute medicine, paediatrics, emergency general surgery and obstetrics. Intensive care has not been explored in its own right as admission to this unit is via admissions through emergency or elective medical and surgical services and so disproportionate need for this service will be covered in the discussion of other acute services.

Please note: the disproportionate use of services/treatments and the disproportionate need of services/treatments can often be interdependent and it is not always possible to disaggregate one from the other.

The report considers each protected characteristic group through:

1. An **evidence review of available literature** which identifies protected characteristic groups who may have a disproportionate need for services. A range of documents have been reviewed including, academic papers, CCG reports and Joint Strategic Needs Assessments (JSNAs).
2. **Demographic analysis** which sets out the characteristics of the study area, and particularly the distribution of residents from different equality groups⁵.
3. **Qualitative in-depth telephone interviews** with 18 individuals. These individuals described the ways in which services are used. They also reflected on the potential impact any service change could have on the local community, specifically those who fall under protected characteristics. These interviews were undertaken with:
 - **12 clinicians and CCG representatives** who described the local context and provided their experiences of delivering services.
 - **6 representatives of key user groups** who discussed the potential impact of any changes to acute services for those they represent.

This information has been used to 'scope in' groups who may have a particular need for the acute services under review. This is not to say that other groups will not need these services, rather it is to suggest that there does not presently exist a body of strong clinical evidence indicating a disproportionate or differential need.

Methodological assumptions and limitations:

It is important to set out the following principles on which this initial EA is based:

- The purpose of the EA is to inform rather than decide. The objective is not to determine the decision, but to assist decision makers by providing better information.
- It is not the purpose of the EA to justify, defend, or challenge the rationale or principles behind potential changes to acute services within ESTH. The EA is being undertaken based on the assumption that any emerging changes to services will be designed by the local commissioners with the objective of realising benefits for all people requiring the services under review, thereby helping to improve outcomes for patients overall.
- The purpose of this initial EA report is not to produce a set of firm conclusions; rather it is to highlight equality groups and their need for acute service. Though doing this, the report should act as a means of outlining which groups may experience potential impacts and highlighting issues that need to be further investigated.
- This initial EA report is based on review and analysis of available secondary data such as publicly available reports, policies, and literature. The protected characteristics identified in this report as having a disproportionate need for the services under review are not considered to be an exhaustive or definitive list at this stage. Where other evidence emerges, particularly through further engagement with local equality and community

⁵ We have undertaken a demographic analysis on the following; the population of children (under 16 years); the population of older people (65 and over); the population living with a long-term illness; the population of females (aged 16-44 years); the population from BAME background; indices of multiple deprivation; and the population by sex. This analysis has been based on available data and focused on those groups which are expected to experience a range of impacts across the majority of the acute service,

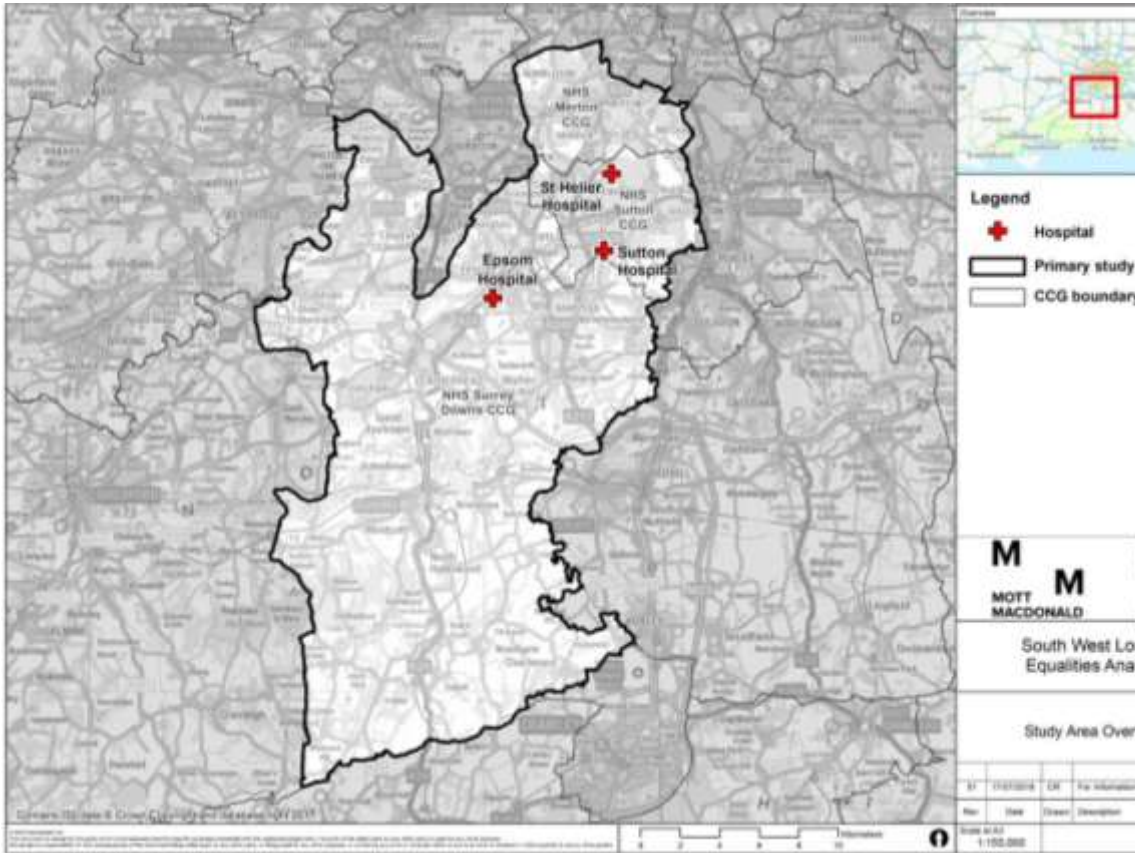

representatives, clinical professionals and other patient groups, these preliminary findings may need to be updated.

- Socio-demographic analysis has been undertaken for the study area to provide an insight into the geographical distribution and concentration of certain key populations. This profiling concentrates on the population groups that have been identified as being sensitive to the proposed changes and those with a 'disproportionate need' or 'differential need' for the services under review, based on the evidence examined to date.
- The latest available census data has been used to complete the demographic analysis. In most cases this means that the 2016 mid-year population estimates have been used, except for demographic information pertaining to the black Asian minority ethnic (BAME) population and limiting-long term illness (which is used as a proxy for disability). In these instances, the 2011 census data has been used.
- Quantification and distribution of impacts are not included. Detailed quantitative analysis of where and which patient groups would be affected by each reconfiguration option does not form part of this report.

1.4 The study area

The primary study area spans the three CCGs that have come together to undertake the Acute Sustainability Programme: Merton, Surrey Downs and Sutton CCGs. However, this report also considers a wider study area to recognise patient movement in and out of the CCGs, which is linked to the proximity of other hospitals to the Trust's main sites. As such, an additional 15km area has also been considered as part of this study. Detailed maps of just the primary study area are provided in Appendices. While hospital sites in the area have been mapped, existing providers of community care have not been. However, a full EA should look to consider the impact of any acute reconfiguration on community care.

Figure 1: Primary study area

Source: Mott MacDonald

The overall population and the density of population provide a baseline from which to break down the key socio-demographic trends in the study area.

1.4.1 Total population

The table below shows the total population of each of the three CCGs, as well as wider area comparators.

Table 1: Total population

Area	All usual residents
Merton CCG	205,029
Surrey Downs CCG	288,199
Sutton CCG	202,220
Primary study area	695,488
Wider study area	6,669,807

Source: LSOA population estimates 2016, ONS

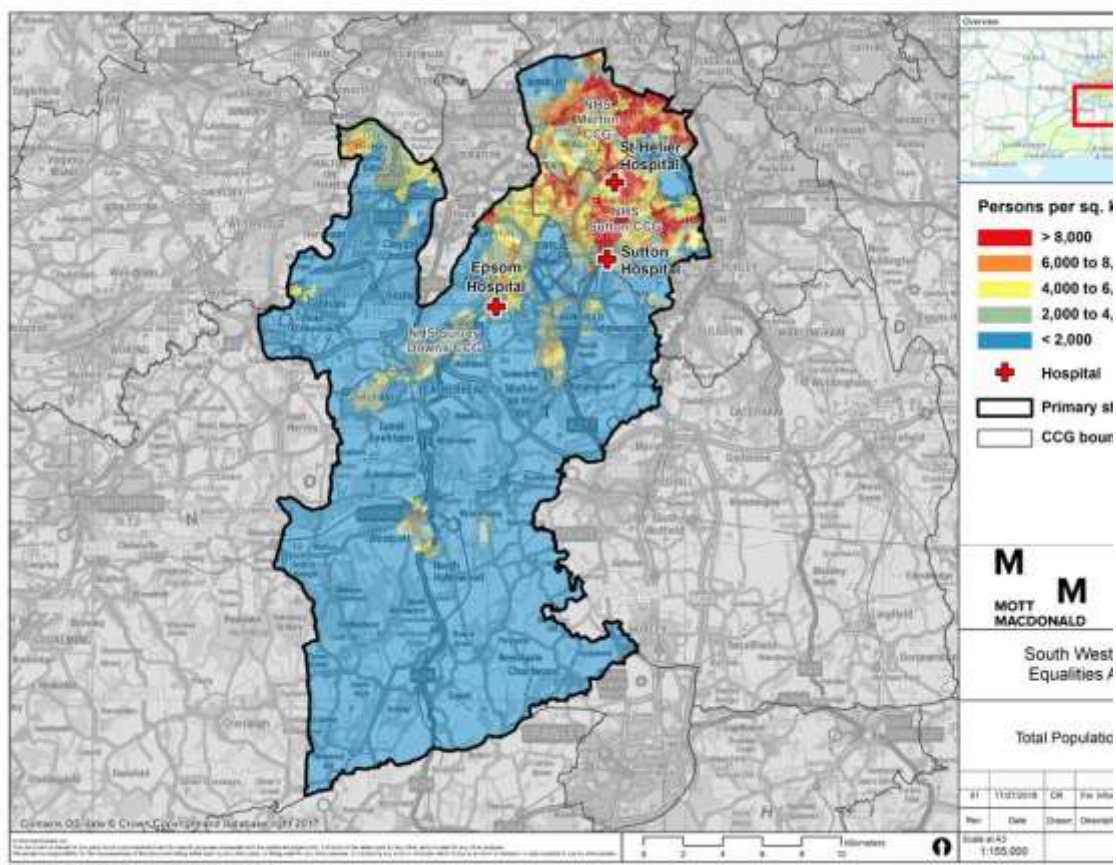

The table indicates that the largest numbers of people live in Surrey Downs CCG (with c.288,000 people), followed by Merton CCG (with c205,000 people) whilst the least populated CCG area is Sutton (with nearly 202,000 people). The total population of the study area is just under c.700,000. The wider study area is over 6 million.

It should also be noted that:

- Merton's population has been projected to increase by around 6.45% between 2014 and 2020. In particular Merton is projected to see a notable growth in those under the age of 16 years and those over 50 years. It is also projected to see a growth in people from a Black, Asian and Minority Ethnic (BAME) background (37% in 2014 to 40% in 2020).⁶
- Surrey Downs' population is estimated to grow by 9% between 2015 and 2025. In particular, Surrey Downs is predicted to see a growth in all ages over 55 while the proportion of people in the 20 to 29 age group set to decrease.⁷
- Sutton's population is forecast to increase by around 12.7% between 2014 and 2024. The population of children and young people aged 0 to 19 years is particularly expected to increase. The proportion of older people aged over 65 is also expected to increase.⁸

1.4.2 Population density

Figure 2: Population density

⁶ Merton (2016) 'Merton Joint Strategic Needs Assessment'. Available at: https://www2.merton.gov.uk/health-social-care/publichealth/jsna/merton-place-people/mpp-people.htm#gla_population_projections_2013_round_trend_based

⁷ Surrey (2015) Surrey Downs CCG Health Profile 2015. Available at: http://www.surreydownscgg.nhs.uk/media/144405/sdccc_health_profile_2015.pdf

⁸ Sutton (2017) Sutton Joint Strategic Needs Assessment: Population fact Sheet'. Available at:

Source: Mott MacDonald

The map above illustrates the overall population density for the study area. It shows that the highest densities of people live predominantly in the north of the area, around Merton and Sutton. Areas located further from London show a lower population density, in part linked to large areas of parkland within the study area, particularly around Epsom. The difference in density between the areas is therefore largely linked to access to services in the Merton and Sutton area.

1.5 Structure of the report

The remainder of the report is structured as follows:

- **Chapter two** provides the scoping review of the equality impacts
- **Chapter three** provides a summary of findings

2 Initial equalities analysis

The following chapter outlines where there has been found to be a differential or disproportionate need across the acute services under review for each of the protected characteristic groups (plus deprivation and carers).

2.1 Age: Children (those aged 16 and under) and younger people (those aged 16-24)

Evidence of disproportionate need / use has been identified for accident and emergency (A&E), obstetrics, and paediatrics.

Table 2: Scoped in services – Children (those aged 16 and under) and younger people (those aged 16-24)

Service Area	Evidence of disproportionate need or disproportionate use	Evidence of differential need
A&E	✓	
Acute medicine		
Emergency general surgery		
Obstetrics	✓	
Paediatrics	✓	

Source: Mott MacDonald, 2018

2.1.1 Demographic profile of children (aged 16 and under)

The table below shows that within the primary study area (covering the three CCGs), the proportion of children aged under 16 (20%) is broadly in line with the national average (19%).

Table 2: Age – children (under 16)

Study area	Total population	Under 16	Under 16 %
Merton CCG	205,029	42,658	21%
Surrey Downs CCG	288,199	57,198	20%
Sutton CCG	202,220	42,143	21%
Study area	695,448	141,999	20%
England	55,268,067	10,529,100	19%

Source: LSOA population estimates 2016, ONS

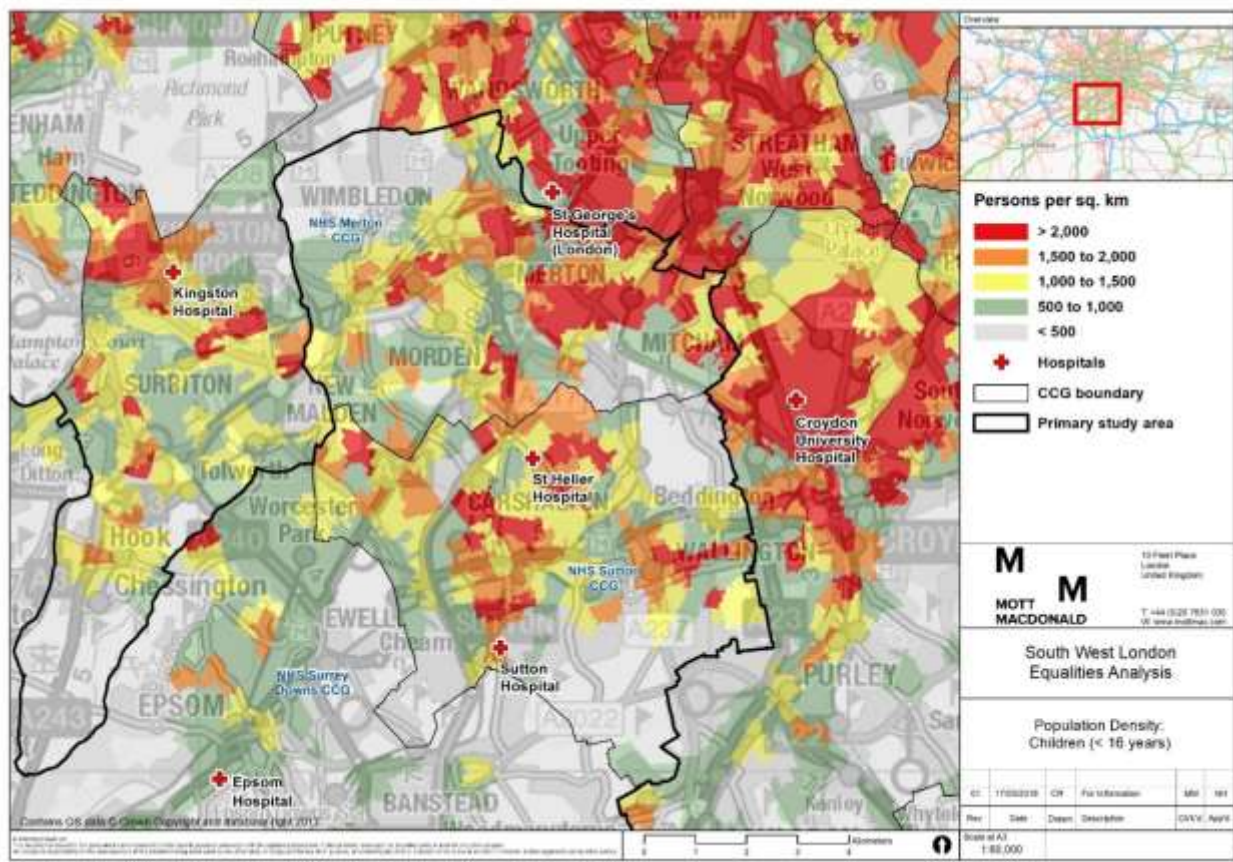

Figures 2 and 3 below shows that most concentrated density of those aged under 16 are located within Merton and Sutton CCGs with the highest densities around Merton and Carshalton. The majority of the study area has a low density of children under 16.

Figure 3: Population density of residents aged under 16 years

Source: Mott MacDonald

Figure 4: Population density of residents aged under 16 years – higher density areas

Source: LSOA population estimates 2016, ONS

2.1.2 Demographic profile of young people (16 to 24 years)

The table below shows that within the primary study area (covering the three CCGs), the proportion of young people aged between 16 to 24 (9%) is consistent across the three CCGs but is below the national average (11%).

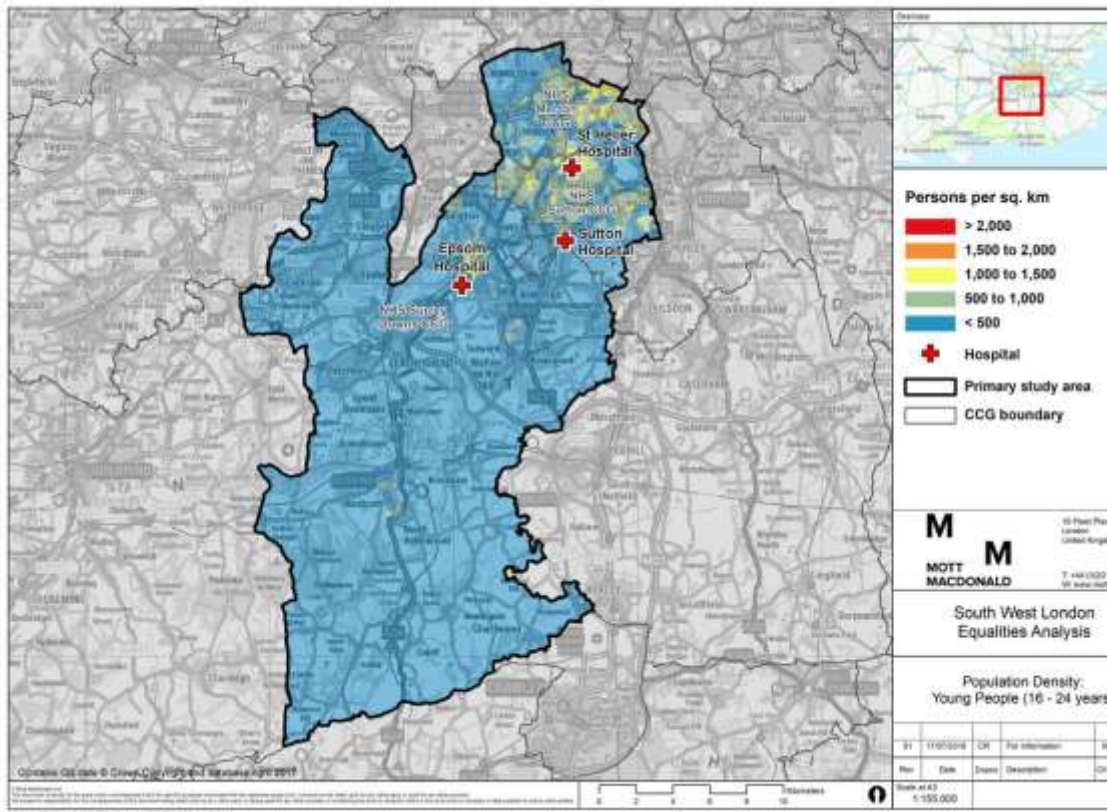

Table 4: Age – 16 to 24

Study area	Total population	16- 24	16-24 %
Merton CCG	205,029	18,153	9%
Surrey Downs CCG	288,199	25,789	9%
Sutton CCG	202,220	18,720	9%
Study area	695,448	62,662	9%
England	55,268,067	6,137,832	11%

Source: LSOA population estimates 2016, ONS

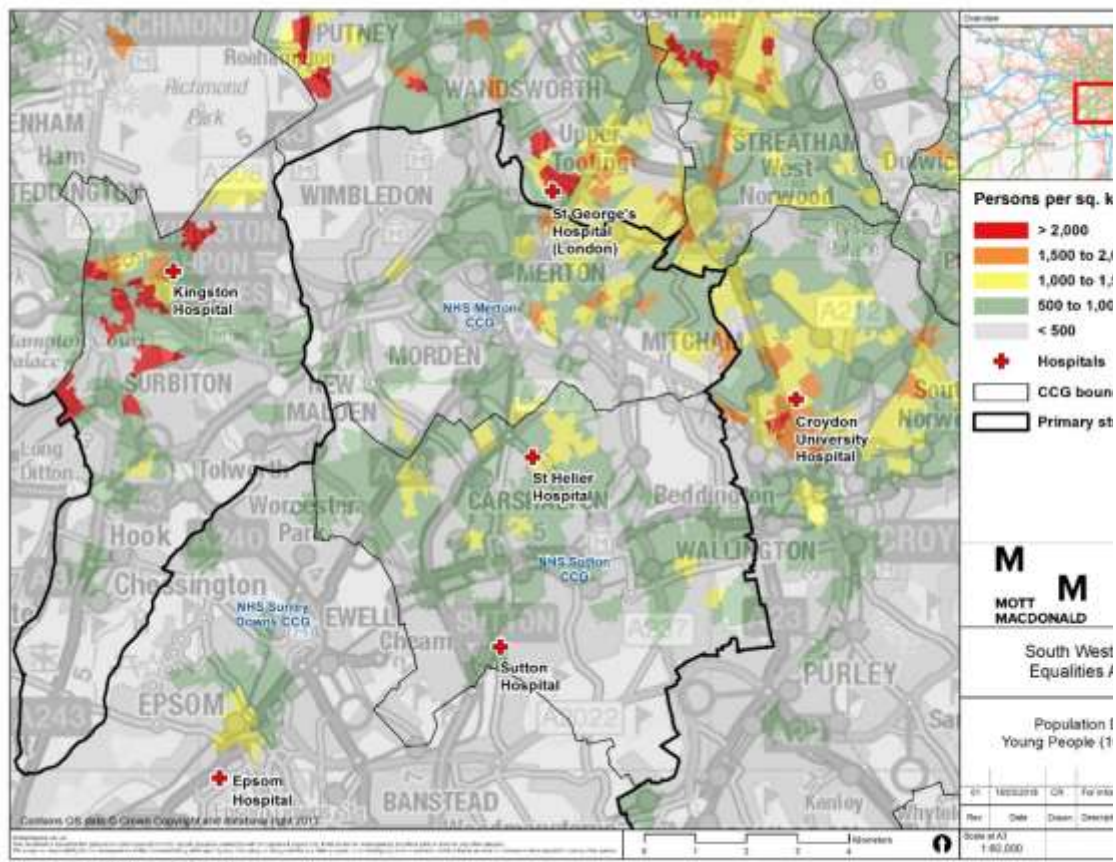

As with the population density for under 16s, figures 4 and 5 below show the largest concentrations of 16 to 24 year olds are in Merton and Sutton CCGs with the highest densities around Merton and Carshalton. The majority of the study area has a low density of young people.

Figure 4: Population density of residents aged 16 to 24 years

Source: Mott MacDonald

Figure 5: Population density of residents aged 16 to 24 years – higher density areas

Source: Mott MacDonald

2.1.3 A&E

There is a disproportionate use of A&E services by children (under 16) indicating that there may also be a disproportionate need for these services. Hospital accident and emergency activity data shows that children comprise of around 21% of attendances at A&E in England while this group represents 19% of the English population.⁹ In addition, estimations of the proportion of emergency department attendances which are unnecessary and potentially avoidable vary from 15% to 40%. Within these estimates the largest subgroup is children presenting with symptoms of minor illness.¹⁰

Moreover, young children make up a disproportionate number of A&E attendances with approximately 10% of A&E attendees in England are aged four or younger. This is higher than the percentage of 0-4-year olds as a proportion of the whole population (8%).¹¹

2.1.4 Obstetrics

Research indicates that adolescent mothers (aged 10 to 19 years) face higher risks of eclampsia, puerperal endometritis, and systemic infections than women aged 20 to 24 years, and babies born to adolescent mothers face higher risks of low birthweight, preterm delivery, and severe neonatal conditions than those born to women aged 20 to 24 years.¹² As such, teenage mothers are more likely to have a disproportionate need for obstetrics.

Pregnant teenagers and young fathers are less likely than older people to access maternity care early in pregnancy (the average gestational booking is 16 weeks while NICE recommends that women be seen by 10 weeks¹³) and are less likely to keep appointments. Research has suggested that this may be attributable to a number of interlocking factors. For example, it has been suggested that young women may:

- not realise they are pregnant;
- take time to come to terms with the pregnancy;
- actively seek to conceal the pregnancy for as long as possible, because of fears about the reaction of her family or peers;
- prioritise other crisis issues such as housing and income over healthcare;
- have a chaotic lifestyle;
- lack a stable address;
- not be able to afford or find transport to a hospital or clinic, especially in rural areas.¹⁴

London has one of the highest rates of teenagers having unwanted pregnancies in the UK¹⁵, although Surrey Downs has relatively low rates.¹⁶ Whilst the number of teenage pregnancies is decreasing (in the last 18 years there has been a 60% reduction in the under-18 conception rate), in 2016 there were 18,076 conceptions to women aged 18 and under in the UK with just over half of these conceptions leading to an abortion (51%)¹⁷. There is also evidence that almost 40% of girls who give birth between the ages of 14 -16 years will give birth again aged 17-19.¹⁸

2.1.5 Paediatrics

As paediatrics is a medical speciality that manages conditions affecting babies, children and young people, by the nature of the service children aged 0-16 years will have a disproportionate need.

2.2 Age: Older people (those aged 65 and over)

Evidence of disproportionate need / use has been identified for A&E, acute medicine and emergency general surgery. Evidence of differential need has also been identified for A&E.

Table 5: Scoped in services – older people (those aged 65 and over)

Service Area	Evidence of disproportionate need or disproportionate use	Evidence of differential need
A&E	✓	✓
Acute medicine	✓	
Emergency general surgery	✓	
Obstetrics		
Paediatrics		

Source: Mott MacDonald, 2018

2.2.1 Demographic profile of older people (those aged 65 and over)

The table below shows that within the three CCGs covered by ESTH, the proportion of those aged 65 and over (16%) is slightly lower than the national average (18%). However, Surrey Downs CCG has a higher than average proportion of older people.

Table 6: Older people (those aged 65 and over)

Study area	Total population	Over 65	Over 65 %
Merton CCG	205,029	25,362	12%
Surrey Downs CCG	288,199	58,608	20%
Sutton CCG	202,220	30,607	15%
Study area	695,448	114,577	16%
England	55,268,067	9,882,841	18%

Source: LSOA population estimates 2016, ONS

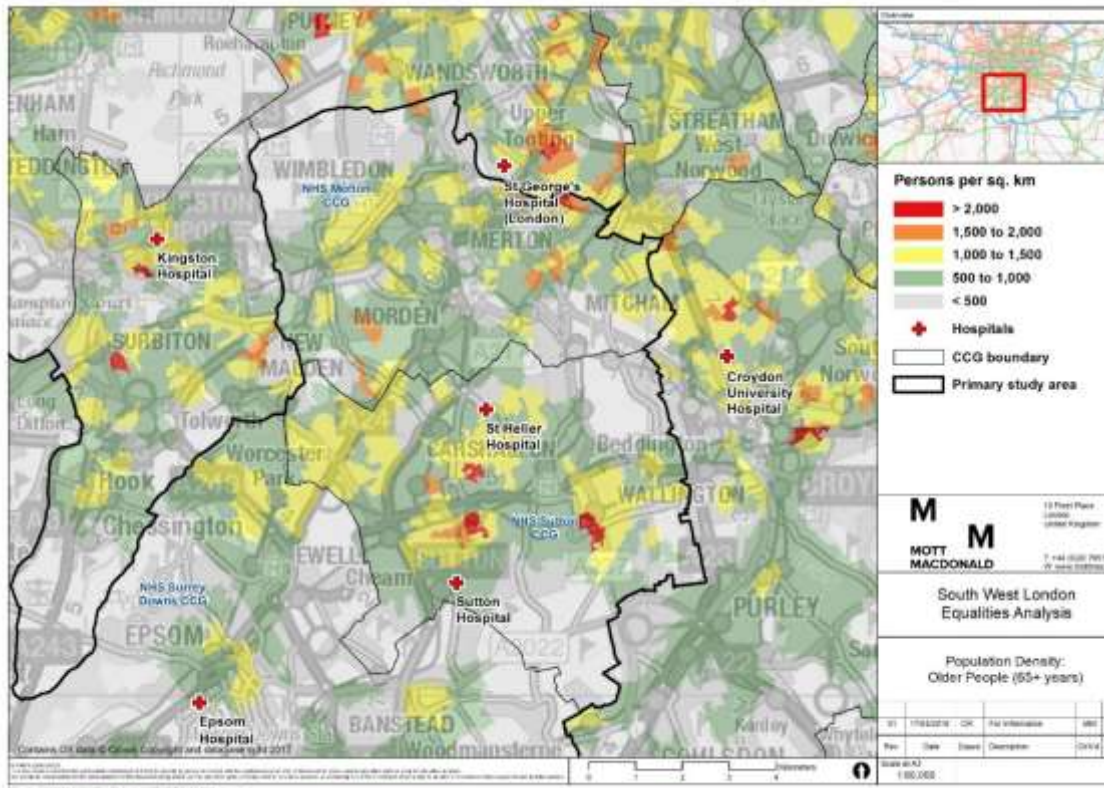

Figures 6 and 7 below indicates that the highest densities of those aged 65 and largely clustered around Sutton and Merton CCG. In particular, Sutton CCG has a number of very high-density areas (over 2,000 per sq. km) located around St Helier and Sutton Hospitals. Despite this, the majority of the primary study area has relatively low densities of people aged 65 and over.

Figure 6: Population aged 65 and over

Source: Mott MacDonald

Figure 7: Population aged 65 and over – higher density areas

Source: Mott MacDonald

2.2.2 A&E

There is a disproportionate use of A&E services by older people. Data on hospital accident and emergency activity has shown that 42% of all A&E attendances in England are from older people while this group represents 18% of the English population. Further, approximately 10% of A&E attendees in England are aged 80 or over, while this group represents 5% of the English population.¹⁹

The population of south west London is predicted to grow over the next 10 years with the greatest increase in older age groups.

In Merton CCG, the 65-84 age group is projected to increase by around 22% and the 85 years and older group is projected to increase by 16%. In Sutton CCG, the 65-84 age group is projected to increase by around 21% and the 85 years and older group is projected to increase by 20%. Finally, for Surrey Downs the 65-84 age group is projected to increase by around 18% and the 85 years and older group is projected to increase by 26%.²⁰ These increases are likely to place greater pressure on A&E services as well as the other scoped-in services in south west London for this group.

Older people may also experience a differential need for A&E services as they are more likely to have complex needs that take longer to resolve. The likelihood of A&E attendees having multiple long-term conditions increases dramatically with age and it was found that people aged 75 years and older spend an average of 213 minutes in A&E compared to 149 minutes for those aged under 75 years.²¹ Stakeholders also reported that older patients may require longer time in services before discharge as they require an increased link with social care and after care arrangements.

2.2.3 Acute medicine

Acute medicine is concerned with the assessment, diagnosis and treatment of adult patients with urgent medical needs. While it is distinct from emergency medicine (A&E) patients who are admitted to hospital from emergency medicine will likely draw on acute medicine.

Over the last few years there has been a steady increase in emergency admissions. Evidence suggested that this is in part linked to an aging population with older people making up more than half of growth in emergency admissions between 2013-14 and 2016-17. Some of this is down to demographic change; between 2013-14 and 2016-17, the number of people aged 65 and over grew by 6.2%. However, over the same period, emergency admissions for people aged 65 and over grew by 12%, almost twice the rate of population growth²². The need for acute medicine is closely tied with emergency admissions. This evidence suggests that older people disproportionately need and use acute medicine.

There is also evidence of a disproportionate need for acute medicine for example, the older a person is, the more likely they are to develop coronary heart disease (treated by acute medicine). The number of deaths caused by cardiovascular disease in 2017 was highest

¹⁹ NHS (2017) 'Hospital Accident and Emergency Activity, 2015-16'. Available at: <https://files.digital.nhs.uk/publicationimport/pub23xxx/pub23070/acci-emer-atte-eng-2015-16-rep.pdf>

²¹ QualityWatch (2014): 'Focus on: A&E attendances. Why are patients waiting longer?'. Available at: https://www.health.org.uk/sites/health/files/QualityWatch_FocusOnA&EAttendances.pdf

²² Department of Health and Social Care, NHS England (2018) 'Reducing emergency admissions'. Available at: <https://www.nao.org.uk/wp-content/uploads/2018/02/Reducing-emergency-admissions-Summary.pdf>

amongst those aged between 75-84 years compared to other age groups.²³ Further, conditions such as pneumonia²⁴ or septicaemia²⁵ are common types of conditions presenting for admission to acute care. They can be developed at any age but are most likely to be in those with weaker immune systems such as older people.

2.2.4 Emergency general surgery

Older people have a disproportionate need for emergency general surgery. They are more likely to develop conditions that require emergency general surgery. The number of patients presenting as an emergency with a general surgical condition increases with age, these conditions include hip fractures, acute pancreatitis, ruptured abdominal aortic aneurysms or conditions that require emergency laparotomy.²⁶

Stomach diseases can result in emergency gastrointestinal surgery and incidence increases sharply with age. Specifically, diverticular disease (related digestive conditions that affect the large intestine) is much more prevalent in older people; with evidence suggesting that by the time people reach 80 years old, they will have some diverticula.²⁷

2.3 Disabled people

Evidence of disproportionate need/use has been identified for A&E, acute medicine, obstetrics and paediatrics.

Table 7: Scoped in services – people living with a disability

Service Area	Evidence of disproportionate need or disproportionate use	Evidence of differential need
A&E	✓	
Acute medicine	✓	
Emergency general surgery		
Obstetrics	✓	
Paediatrics	✓	

Source: Mott MacDonald, 2018

2.3.1 Demographic profile of people living with a disability

The table below shows that within the three CCGs covered by ESTH, the proportion of those with a disability (14%), while in line with London as a whole, is lower than the national average (18%).

A number of stakeholders suggested that the local area has both a high level than national average of people with a learning disability as well as those who have a mental health condition. It was generally felt that the high proportion of people with a learning disability was linked to the area historically having a number of institutions for people with a learning disability. There was less understanding amongst those interviewed as to why there is a high prevalence on mental health conditions in the area, particularly amongst younger people. National data, such as that

²⁶ K.F. Desserud, et al. (2015): 'Emergency general surgery in the geriatric patient'. Available at: <https://www.ncbi.nlm.nih.gov/pubmed/26620724>

²⁷ NHS Choices (no date): 'Diverticular disease and diverticulitis'. Available at: <https://www.nhs.uk/conditions/diverticular-disease-and-diverticulitis/>

produced by the GP Patient Survey²⁸, does not indicate variation with the national average for those with a mental health condition or with a learning disability. However, local JSNA information suggests that there has been under recording of these conditions across the CCGs. In particular, Surrey Downs has indicated that Surrey has historically had large numbers of long stay hospitals and the placement of large numbers of people, from both inside and outside the county, into these hospitals during the last century, and their subsequent closure, has disproportionately increased the proportion of people with a learning disability in the general population when compared with other areas.²⁹

Table 8: People living with an Limiting Long-Term Illness (LLTI).

Study area	Total population	LLTI	LLTI %
Merton CCG	199,693	25,232	13%
Surrey Downs CCG	280,125	38,097	14%
Sutton CCG	190,146	27,189	14%
Study area	669,964	90,518	14%
England	53,012,456	9,352,586	18%

Source: Census 2011, ONS

Figures 8 and 9 below shows that the highest densities of people living with a disability are largely clustered around Sutton and Merton CCG. In both CCGs the density of people living with a disability tend to be highest in the areas located closest to a hospital (St George's, St Helier or Sutton).

2.3.2 A&E

People living with some types of disability tend to have a disproportionate need for A&E services. People with Down's syndrome are a particular high-risk group, because they have a predisposition to lung abnormalities, a poor immune system and a tendency to breathe through their mouth.³⁰ Indeed many of the conditions identified as ambulatory care sensitive conditions (ACSCs), for example convulsions and epilepsy, and respiratory diseases, are more common among people with learning disabilities which can put this group at risk of requiring emergency care.³¹

People with other types of disability tend to disproportionately use A&E services. For example, users of mental health services are more than twice as likely to have attended A&E than non-users.³² Research suggests that increased A&E service use among people with mental health problems is due to unmet health-related needs and an increased vulnerability to accidents and

self-harm.³³ Local stakeholders also reported higher usage of services by those with mental health conditions.

2.3.3 Acute medicine

Disabled people often have a disproportionate need for treatment as a result of, though not necessarily associated with, their disability. For example, respiratory disease is the main cause of death in people with learning disabilities and is much higher than the general population. People with a learning disability also have a higher risk of respiratory tract infections caused by aspiration or reflux if they have swallowing difficulties.³⁴

Research undertaken by St George's hospital has shown that adults with intellectual disabilities are likely to disproportionately use acute medicine services, experiencing twice as many emergency hospital admissions overall compared to the general population.³⁵ The research found that of those with intellectual disabilities, 23% had an emergency admission compared to 12% of those in the control group. The overall annual rate for emergency hospitalisations in adults with intellectual disabilities was 182 per 1,000 adults, nearly three times higher than the comparable group when adjusted for comorbidities, smoking and deprivation.

Further, other long-term disabilities, for example Alzheimer's, can also result in higher levels of emergency admissions, and subsequently a disproportionate use and need for acute medicine. In particular, these patients are more likely to suffer from falls and other accidents. In 2012/13, 73% of hospital admissions for Alzheimer's sufferers were emergency admissions.³⁶

Finally, a 2013 study into the effect of mental health conditions on unplanned admissions found that patients with a mental health disorder were more likely than patients without a mental health disorder to have unplanned admissions (10.8% compared to 4.5%) or potentially preventable unplanned admissions (2.1% compared to 0.8%).³⁷ This links closely with views expressed by local stakeholders who reported disproportionate need and use of services by those with mental health problems, linked to issues around access and contacting services only when at a critical stage.

2.3.4 Obstetrics

Existing studies evidence that disabled women disproportionately use maternity services more than non-disabled women for example, physically disabled women disproportionately use ante and postnatal services. Those with sensory impairments are more likely to have met staff before labour. Women with mental health disabilities tend to disproportionately use services and with a greater need for communication and support.³⁸

Women with long term conditions may have a disproportionate need for obstetric services as they are at a higher risk of developing complications during pregnancy. Women with type 1

diabetes can develop problems with their eyes (diabetic retinopathy) and their kidneys (diabetic nephropathy) or find that existing problems get worse. Women with pre-existing type 1 or type 2 diabetes are also at higher risk of having babies who: do not developing normally/have congenital abnormalities; are stillborn or die soon after birth; have health problems shortly after birth, such as heart and breathing problems which require hospital care. Furthermore, drugs taken to treat the pre-existing condition might have to be altered during pregnancy which can cause complications for the mother.³⁹

Babies born to women with some chronic illnesses, such as rheumatoid arthritis, and mental health conditions, such as schizophrenia are more likely to have a low birthweight in comparison to babies born to other women.⁴⁰

Barriers in access to healthcare providers and facilities have been reported for many women with physical disabilities and mental health conditions, resulting in higher rates of abortion, miscarriage, caesarean section and low usage of contraception.

2.3.5 Paediatrics

Disabled children have a disproportionate need for paediatric services as they are likely to have poorer overall health and less access to adequate healthcare in comparison to children without a disability.⁴¹ The needs of disabled children, young people, and their families are unique to them, they include issues to do with stamina, breathing, fatigue, social and behavioural impairments. These require multi-disciplinary response across paediatrics. There is also evidence to suggest that disabled children are likely to have multiple complex needs, for example, it is estimated that up to 40% of hearing impaired children have an additional disability or that 10% of patients with paediatric congenital heart disease have some form of learning disability.^{42 43}

2.4 Gender re-assignment

Evidence of disproportionate need/use has been identified for A&E.

Table 9: Scoped in services – gender re-assignment

2.4.1 Demographic profile – gender reassignment

Census information on the geographical distribution of the trans community is not available.

At present, there is no official estimate of the trans population. The Gender Identify Research and Identity Society (GIREs) in their Home Office funded study in 2009, estimated that the number of trans people in the UK to be between 300,000 - 500,000.⁴⁴ Most recent estimates are that in the UK, around 650,000 people, 1% of the population, are estimated to experience some degree of gender non-conformity (GIREs).⁴⁵

In south west London, this equates to approximately 14,400 people.

2.4.2 A&E

There is evidence to suggest that transgender people have a disproportionate need for emergency care. The UK's largest survey of transgender people revealed that 34% of transgender people have attempted suicide.⁴⁶ The increased likelihood of attempting suicide could lead to a greater proportion of trans people presenting at A&E departments for emergency intervention.

There is also evidence to suggest that transgender people disproportionately use A&E departments. Research which grouped lesbian, gay, bisexual and transgender (LGB&T) people, found that they are also less likely to access some health services in favour of using A&E departments compared to the general public.⁴⁷

2.5 Marriage and civil partnership

The evidence review does not indicate any disproportionate or differential need for this protected characteristic group.

2.6 Pregnancy and maternity

Evidence of disproportionate need/use has been identified for acute medicine, obstetrics and paediatrics.

Table 10: Scoped in services – pregnancy and maternity

Service Area	Evidence of disproportionate need or disproportionate use	Evidence of differential need
A&E		
Acute medicine	✓	
Emergency general surgery		
Obstetrics	✓	
Paediatrics	✓	

Source: Mott MacDonald, 2018

2.6.1 Demographic profile – pregnancy and maternity

To analyse levels of pregnancy and maternity in the study areas data have been used on the number of women aged 16-44 within the population. The table below shows that within the study area, the number of women aged 16-44 (19%) is in line with the national average (19%). However, Surrey Down has a lower than the national average proportion of females aged 16-44 (16%) while Merton has slightly higher than average proportion (22%).

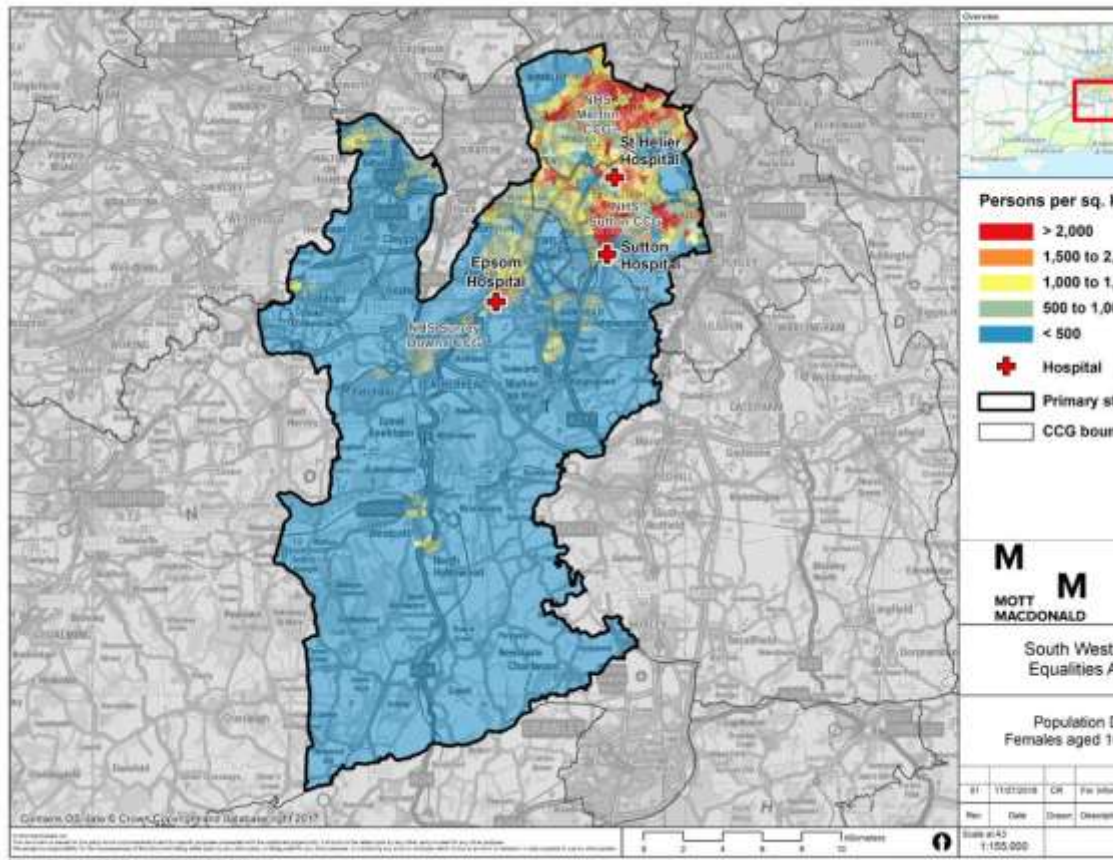

Table 11: Population of females aged 16-44

Study area	Total population	Females aged 16-44	Females aged 16-44 %
Merton CCG	205,029	45,013	22%
Surrey Downs CCG	288,199	46,372	16%
Sutton CCG	202,220	40,132	20%
Study area	695,448	131,517	19%
England	55,268,067	10,313,687	19%

Source: LSOA population estimates 2016, ONS

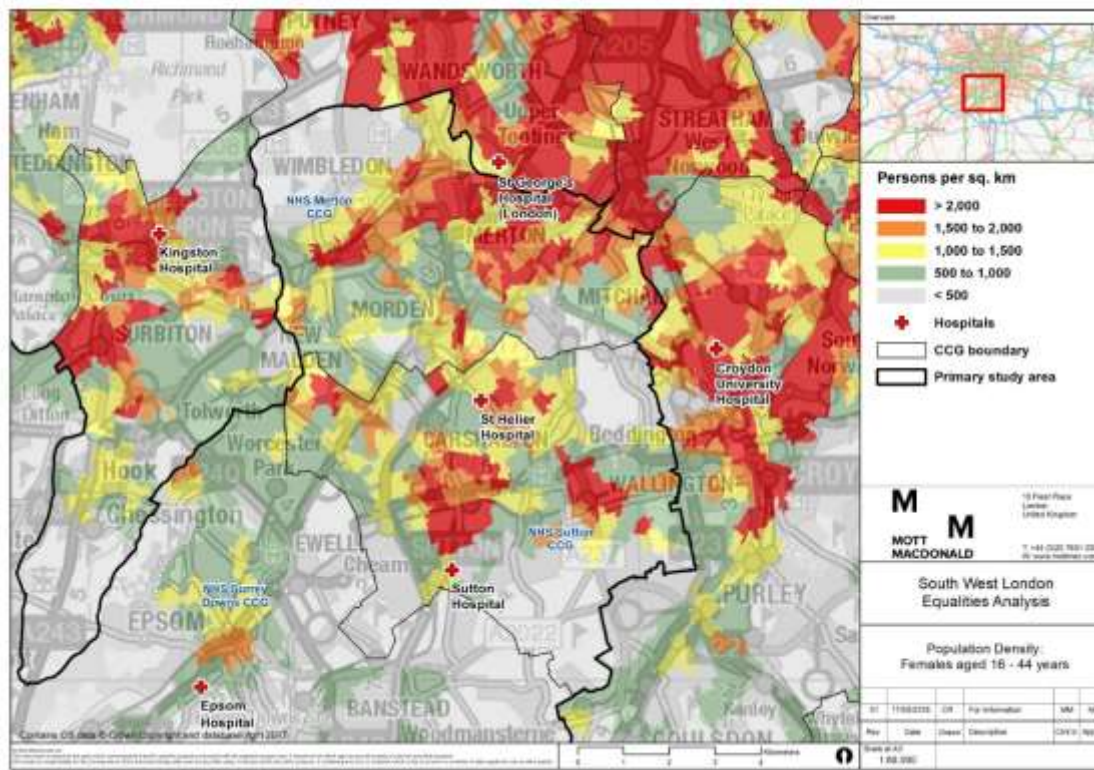

Figures 10 and 11 below shows that high densities of females aged 16-44 in both Sutton and Merton CCG with Sutton with the highest density clustered around Merton and nearest to St George's hospital.

Figure 10: Population of females aged 16-44

Source: Mott MacDonald

Figure 11: Population of females aged 16-44

Source: LSOA population estimates 2016, ONS

2.6.2 Acute medicine

Women who are in the early stages of pregnancy are likely to have a disproportionate need for acute medicine as they would be likely that they would be admitted to hospital as an emergency admission in the event of heart failure. Women who are in the early stages of pregnancy are more at risk of developing heart disease than women who are not pregnant. Heart disease is the biggest single cause of maternal deaths in the UK as there is a 50% increase in how much the heart has to do by the end of the first trimester, which needs to be sustained for six months.⁴⁸

2.6.3 Obstetrics

By the very nature of these service areas, women who are pregnant, new mothers, or breastfeeding will experience disproportionate need for this type of care. In 2016 85% of births in England were in an obstetric unit.⁴⁹

⁴⁸ British Heart Foundation (date unknown) 'Pregnancy and heart disease'. Available at: <https://www.bhf.org.uk/heart-matters-magazine/medical/women/pregnancy-and-heart-disease>

⁴⁹ National Maternity Review (2016) 'Better Births: Improving outcomes of maternity services in England'. Available at: <https://www.england.nhs.uk/wp-content/uploads/2016/02/national-maternity-review-report.pdf>

2.6.4 Paediatrics

By the very nature of these service areas, women who are pregnant, new mothers, or breastfeeding will experience disproportionate need for paediatric services at post-partum. For example: monitoring of growth and developed of their new-born and anticipatory guidance.⁵⁰

2.7 Race and ethnicity

Evidence of disproportionate need/use has been identified for A&E, acute medicine and obstetrics.

Table 12: Scoped in services – race and ethnicity

Service Area	Evidence of disproportionate need or disproportionate use	Evidence of differential need
A&E	✓ (BAME & White British White Other)	
Acute medicine	✓ (BAME)	
Emergency general surgery		
Obstetrics	✓ (BAME)	
Paediatrics	✓ (BAME)	

Source: Mott MacDonald, 2018

2.7.1 Demographic profile – race and ethnicity

The table below shows that within the study area, the proportion of those from BAME backgrounds is (30%) this is higher than the national average (20%). Within the three CCGs, over half of Merton CCG have a BAME background while Surrey Downs has below the national average (16%).

Table 13: Population of people from BAME backgrounds

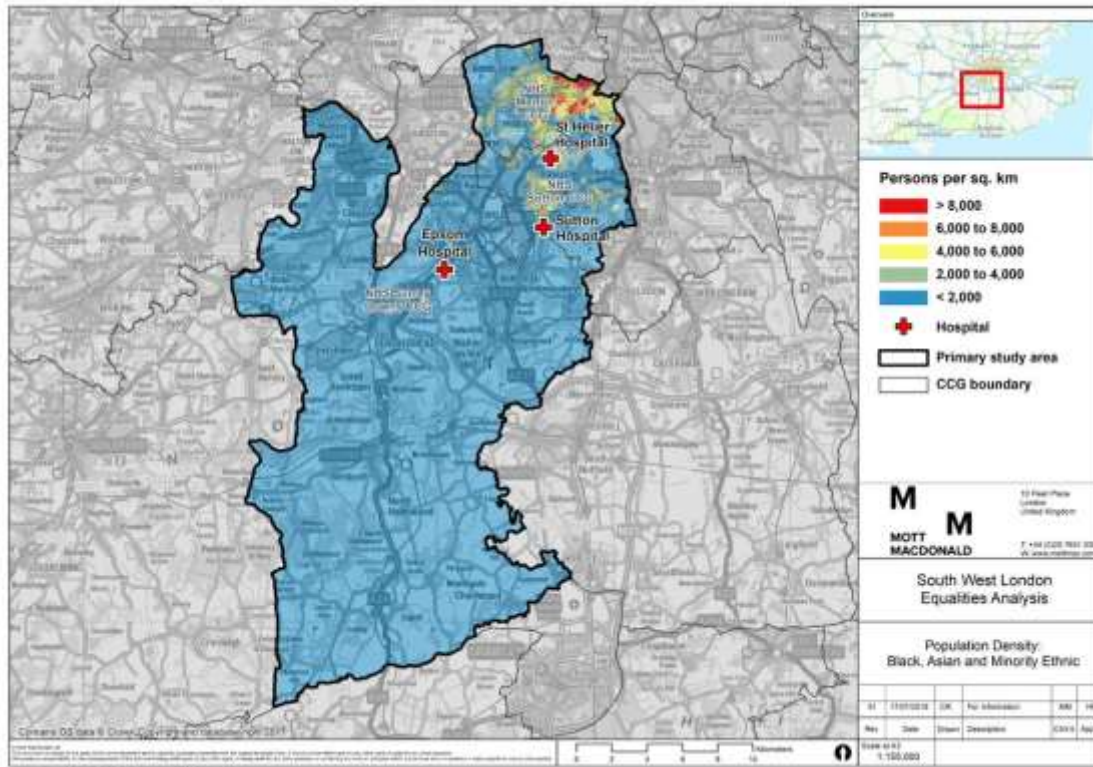

Study area	Total population	BAME	BAME %
Merton CCG	199,693	103,035	52%
Surrey Downs CCG	280,125	44,543	16%
Sutton CCG	190,146	55,292	29%
Study area	669,964	202,870	30%
England	53,012,456	10,733,220	20%

Source: Census 2011, ONS

Figures 12 and 13 below shows that the high density of people from BAME backgrounds is in Merton CCG with most the main hotspot being within Merton. Although overall, the study area has relatively low densities of people from BAME backgrounds.

Figure 12: Population of people from BAME backgrounds

Source: Mott MacDonald

Figure 13: Population of people from BAME backgrounds – higher density areas

Source: Census 2011, ONS

2.7.2 A&E

2.7.2.1 BAME

Members of minority ethnic groups disproportionately use A&E, as they are more likely to present at A&E in comparison with those who are not part of a minority ethnic group. People from ethnic minority groups experience or perceive barriers in accessing primary care services.⁵¹ This is corroborated by lower GP registration rates among this group.⁵² This increased use of A&E has been shown within the study area. Local audits found that people from migrant communities were least likely to be registered with a GP and more likely to use A&E, even during normal working hours.⁵³

Local stakeholders reported greater use of A&E by those people from ethnic minority groups, linking this to increased levels of deprivation within the local communities and reduced access to other health services due issues such as language barriers.

⁵¹ Gibin, P. et al. (2011): 'Names-based classification of accident and emergency department users'. Available at: <https://pdfs.semanticscholar.org/7c53/2d61afaddf9c5140531528eadfd8885fc8a.pdf>

⁵² ibid

⁵³ HSJ (2012) 'How to reduce A&E use by targeting diversity'. Available at: <https://www.hsj.co.uk/technology-and-innovation/how-to-reduce-aande-use-by-targeting-diversity/5052217.article>

2.7.2.2 White British, White Other

Other White British, White Irish and Other White Groups have higher risk ratios for appendicitis.⁵⁴ In 2014-15, 97% of hospital admissions for appendicitis were emergency admissions⁵⁵, indicating a disproportionate need for this group.

2.7.3 Acute medicine

2.7.3.1 BAME

Evidence indicates that people from a BAME background have a disproportionate need for acute medicine. For example:

- People of South Asian background are three times more likely to require an emergency hospital admission for asthma, while people from an African Caribbean background are twice as likely to require emergency admission.⁵⁶ One reason attributed to south Asian men having a higher risk of respiratory disease is linked to a higher propensity to smoke compared to members of other minority ethnic backgrounds.⁵⁷
- People of South Asian background also have the highest rate of coronary heart disease; people from an African Caribbean background have a higher risk of developing high blood pressure; and the prevalence of type-2 diabetes (which may cause complications to acute medical care) for both people of African Caribbean and South Asian ethnicity is much higher than in the rest of the population.⁵⁸
- Gypsy Travellers, of which there is a high population in Surrey Downs, are more likely to experience high rates of undiagnosed hypertension; local research in Surrey Downs found that 52% had high blood pressure.⁵⁹

Local stakeholders referenced that the local Sri Lankan and African communities tend to have an increased incidence of diabetes and heart disease – translating into an increase need for acute services.

2.7.4 Emergency general surgery

2.7.4.1 BAME

Local research with the Gypsy Roma and Traveller community in Surrey Downs identified high levels of smoking (48%) amongst the community.⁶⁰ This is associated with the need for

⁵⁴ Bhopal RS, et al (2014) 'Ethnic variations in five lower gastrointestinal diseases: Scottish Health and Ethnicity Linkage Study'. Available at: <http://bmjopen.bmj.com/content/4/10/e006120>

⁵⁵ This percentage has been calculated using the statistics from HES Admitted Patient Care, England 2014-15. Of 44,653 recorded admissions, 43,120 were emergency admissions. For the data set please see: <http://content.digital.nhs.uk/searchcatalogue?productid=19420&q=title%3a%22Hospital+Episode+Statistics%2c+Admitted+patient+are+-+England%22&sort=Relevance&size=10&page=1#top>

⁶⁰ Surrey Downs CCG (2015): 'Surrey Downs CCG Health Profile 2015'. Available at: http://www.surreydownsccg.nhs.uk/media/144405/sdccc_health_profile_2015.pdf

emergency surgical services due to the development of cancers and other lung diseases associated with smoking.

2.7.5 Obstetrics

2.7.5.1 BAME

Those from a BAME background are likely to have a disproportionate need for obstetric services and use of obstetric services. The percentage of live births in England and Wales to mothers born outside the UK has increased every year since 1990 (when it was 11.6%) reaching 28% in 2016. It has been suggested that this trend in higher proportions of births to women born outside the UK, has in part been linked to better fertility levels among foreign-born women⁶¹. Other research suggests that certain sections of the UK's South Asian population – most notably Pakistani and Bangladeshi communities – are more likely to have large families, and therefore high fertility and birth rates are common.⁶² Numerous population studies have revealed this trend and stakeholders also reported this in interviews.

Women from an ethnic minority have a disproportionate need for obstetric services, due to an increased risk of maternal death. The most recent data analysed by the Maternal, Newborn and Infant Clinical Outcome Review Programme found that women from a minority ethnic background continue to have an increased risk of maternal death compared to White women.⁶³ Evidence suggested that this is linked to health seeking behaviour and quality of care. This is often further linked to issues around accessing health services for reasons such as language barriers.⁶⁴ In Merton just under 60% of babies were born to mothers who were born outside⁶⁵ the UK and in Sutton 40% were born to mothers born outside of the UK⁶⁶. For both CCGs⁶⁷ this is significantly higher in comparison to the rest of England.

2.7.6 Paediatrics

2.7.6.1 BAME

Those from a minority ethnic background have a disproportionate need for children's services and specialist care within paediatrics. Babies are twice as likely to die before the age of one if the mother was born in Pakistan or the Caribbean compared to mothers born in the UK. This indicates that babies of migrants from Pakistan or the Caribbean are likely to be high users of paediatric services.⁶⁸

Research also suggests that babies from minority ethnic background are more likely to require care in a neonatal or specialist care baby unit as they are at higher risk of infant mortality and lower birth weights: in 2014-15, 9.5% of babies from an Asian background were recorded as

⁶¹ ONS (2016) 'Births by parents' country of birth, England and Wales: 2016'. Available at: <https://www.ons.gov.uk/peoplepopulationandcommunity/birthsdeathsandmarriages/livebirths/bulletins/parentscountryofbirthenglandandwales/2016>

having a low birth weight (under 2.5kg). Compared to 8.4% for Black babies and 6.2% for those from a White background.⁶⁹

The incidence of patients from black and minority ethnic (BME) communities with paediatric congenital heart disease is greater than the general population.⁷⁰

2.8 Religion and belief

The evidence review does not indicate any disproportionate or differential need for this protected characteristic group.

2.9 Sex

Evidence of disproportionate need/use has been identified for acute medicine (males) and obstetrics (females). Evidence of differential need has been identified for A&E and emergency general surgery.

Table 14: Scoped in services – sex

Service Area	Evidence of disproportionate need or disproportionate use	Evidence of differential need
A&E		✓
Acute medicine	✓ (male)	
Emergency general surgery		✓
Obstetrics	✓ (female)	
Paediatrics		

Source: Mott MacDonald, 2018

2.9.1 Demographic profile – sex

The table below shows that the number of men and women living within the primary study area is the same as the national average (49% and 51% respectively).

Table 15: Sex

Study area	Total population	Males	Males %	Females	Females %
Merton CCG	205,029	100,780	49%	104,249	51%
Surrey Downs CCG	288,199	140,050	49%	148,149	51%
Sutton CCG	202,220	98,593	49%	103,627	51%
Study area	695,448	339,423	49%	356,025	51%
England	55,268,067	22,300,920	49%	27,967,147	51%

⁷⁰ NHS England (2016) 'Paediatric Congenital Heart Disease Specification'. Available at: <https://www.england.nhs.uk/commissioning/wp-content/uploads/sites/12/2016/03/paed-spec-2016.pdf>

2.9.2 A&E

Men and women have differential needs for A&E services as they are likely to suffer from different conditions which require access to these services. Gender differences in A&E attendance also vary by age group⁷¹:

- Boys aged 0-14, are more likely to attend A&E
- Women aged 15-34, are more likely to attend A&E overall - although there are specific incidents and cases where men are more likely to present at A&E.
- Men aged 35 upwards, are more likely to attend A&E overall

As well as differences by age men and women suffer from different health issues which are more likely to bring them into contact with A&E. For example:

- Men are six times more likely to have an abdominal aortic aneurysm than women.
- Men are also at higher risk of certain injuries than women. For example, men are more likely to be involved in road traffic accidents (RTAs) than women (RTAs make up 1.2%⁷² of total attendances at A&E).⁷³ Research conducted by Brake, a road safety charity, found that men are more likely to hold a range of attitudes that are linked with dangerous or risk-taking behaviours⁷⁴, and therefore more likely to be involved in RTAs than women.
- In comparison to men, women are four times more likely to suffer from hip fractures which is one of the likely risk factors of osteoporosis.⁷⁵

2.9.3 Acute medicine

A disproportionate need for acute medicine is found for men. Evidence suggests that men consult with their GP less than women and prolonged avoidance increases the risk that illness will require acute treatment.⁷⁶ Further, research shows that, compared to women, men are:

- 28% more likely to be hospitalised for congestive heart failure;
- 32% more likely to be hospitalised for long-term complications of diabetes;
- 24% more likely to be hospitalised for pneumonia.⁷⁷

2.9.4 Emergency general surgery

Men and women have differential needs for emergency general surgery:

⁷⁷ Jenna L. Davis (2016) 'The "Superman Syndrome": Why Men Are Reluctant to Pursue Preventive Care'. Available at: <http://www.primaryissues.org/2011/06/mens-health/>

- Men are at higher risk of certain injuries than women (for example, men are more likely to be involved in RTAs than women⁷⁸). Injuries such as these are more likely to lead to a referral on to treatment in emergency general surgery.⁷⁹
- Duodenal ulcers are twice as common in men than in women. Men are also more likely to develop alcohol-related pancreatitis.⁸⁰
- Gallstone related diseases account for around a third of emergency general surgery admissions and referrals.⁸¹ Women are more likely to develop gallstones, particularly if they have had children, are taking the combined pill or are undergoing high-dose oestrogen therapy.⁸²

2.9.5 Obstetrics

By the very nature of these service areas, women will experience disproportionate need for this type of care. In 2016 85% of births in England were in an obstetric unit.⁸³

2.10 Sexual orientation

Evidence of disproportionate need/use has been identified for A&E.

Table 16: Scoped in services – sexual orientation

Service Area	Evidence of disproportionate need or disproportionate use	Evidence of differential need
A&E	✓	
Acute medicine		
Emergency general surgery		
Obstetrics		
Paediatrics		

Source: Mott MacDonald, 2018

2.10.1 Demographic profile – sexual orientation

Census information on the geographical distribution of people on the basis of their sexual orientation is not available.

2.10.2 A&E

There is evidence to suggest that lesbian, gay and bisexual (LGB) people have a disproportionate need for emergency care. Self-harm and thoughts of suicide are more common among people who are lesbian, gay and bisexual compared to those who are heterosexual.⁸⁴

The increased likelihood of attempting suicide could lead to a greater proportion of LGB presenting at A&E departments for emergency intervention.

⁷⁸ For more detail please see section 2.10.1 Accident and emergency

⁸⁴ The National LGB&T Partnership (2015) 'The Adult Social Care Outcomes Framework: lesbian, gay, Bisexual and Trans Companion Document'. Available at: <https://nationallgbtpartnershipdotorg.files.wordpress.com/2015/08/ascof-companion-piece.pdf>

There is also evidence to suggest that LGB disproportionately use A&E departments. LGBT people were less likely to access some key health services (76 per cent used GP surgeries, compared with 90 per cent of the general population), but were more likely to have used accident and emergency services and minor injuries clinics (18 per cent and 12 per cent respectively) in comparison to the general population.⁸⁵

2.11 Carers

The latest figures available state that:

- In Surrey Downs it is estimated that there are around 28,000 carers⁸⁶
- In Sutton it is estimated that there are around 18,298 carers⁸⁷
- In Merton there is thought to be approximately 17,000 carers⁸⁸

It is commonly accepted that documenting the number of carers is difficult as many carers are unidentifiable. Therefore it is highly likely that the true number of carers is likely to be much higher.

The evidence review does not indicate any disproportionate or differential clinical need for this group. However, carers are important within the study area and there are increased risks associated with being a carer such as the risk of back injuries, higher blood pressure and increased risk of stroke.⁸⁹ It was suggested by stakeholders that carers will be disproportionately impacted by changes to services when considering the likely travel impact some may experience from local acute services moving. Stakeholders stated that carers would struggle with the additional cost and difficulty in arrange travel to a different site which could impact on physical, emotional and mental wellbeing. This should be considered in the context that carers have been known to prioritise the care of those they care for, meaning that are less likely to access services such as primary care for their own needs. Challenges in finding someone to replace their caring responsibilities whilst they receive care may also reduce access to services. It is also suggested that carers may also be more likely to experience mental health conditions due to the anxiety and stress carers commonly suffer.

2.12 Deprivation

Evidence of disproportionate need has been identified for all services.

Table 17: Scoped in services – deprivation

Service Area	Evidence of disproportionate need or disproportionate use	Evidence of differential need
A&E	✓	
Acute medicine	✓	
Emergency general surgery	✓	
Obstetrics	✓	
Paediatrics	✓

⁸⁹ Surrey Downs CCG (2015): 'Surrey Downs CCG Health Profile'

2.12.1 Demographic profile – deprivation

The table below shows that the proportion of people residing in the most deprived quintile in the study area (3%) is below the national average (20%).

The least deprived quintile in the study area (45%) exceeds the nation average (19%) in all three CCGs, with Surrey Downs (65%) having the largest population who sit within the least deprived quintile.

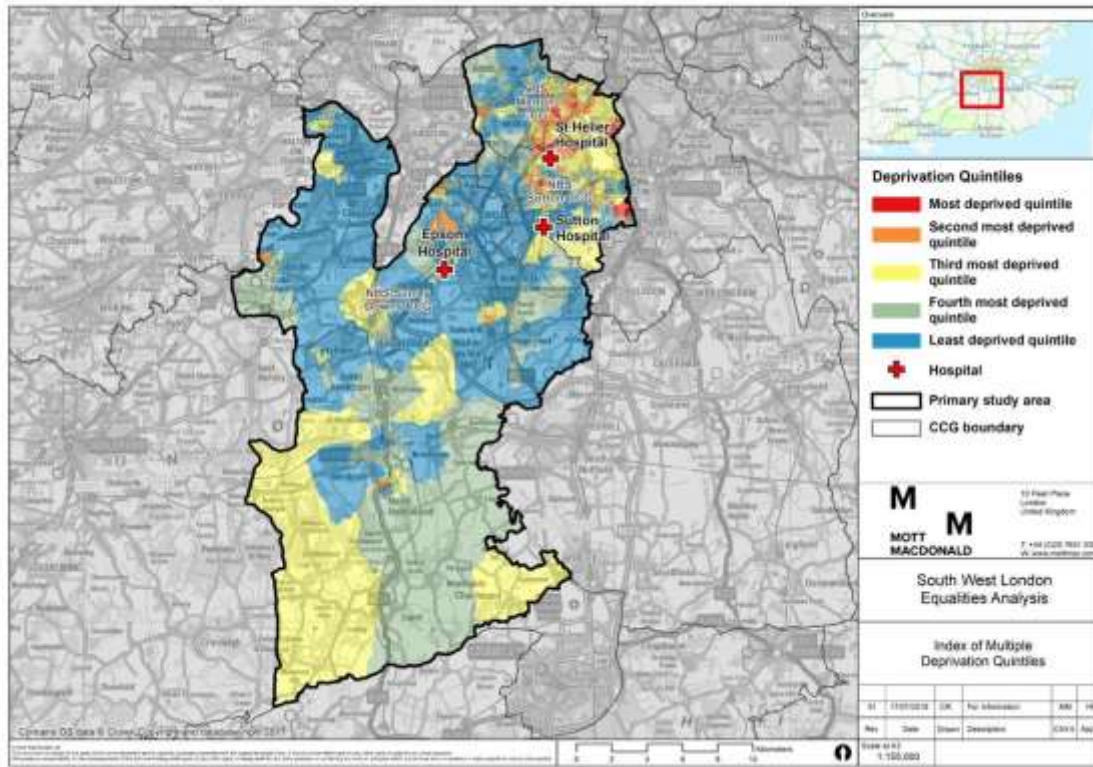

Table 18: Deprivation quintiles

CCG	Most deprived quintile	Second most deprived quintile	Third most deprived quintile	Fourth most deprived quintile	Least deprived quintile
Merton CCG	6,436 (3%)	43,937 (21%)	46,478 (23%)	46,876 (23%)	61,302 (30%)
Surrey Downs CCG	0 (0%)	12,889 (4%)	33,638 (12%)	53,100 (18%)	188,572 (65%)
Sutton CCG	11,113 (5%)	30,125 (15%)	45,082 (22%)	54,721 (27%)	61,179 (30%)
Study area	17,549 (3%)	86,951 (13%)	125,198 (18%)	154,697 (22%)	311,053 (45%)
England	11,239,243 (20%)	11,382,030 (21%)	11,090,316 (20%)	10,895,919 (20%)	10,660,559 (19%)

Source: IMD 2015

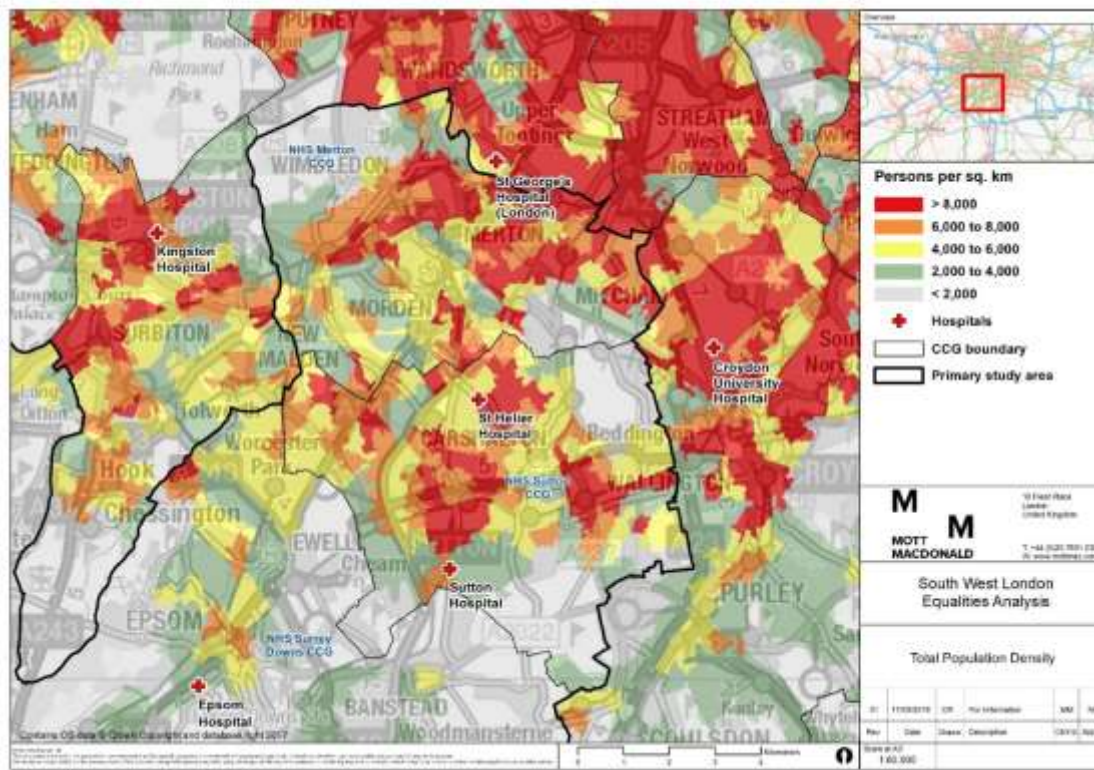

Figures 14 below shows distribution of the deprivation quintiles across the study area. The most deprived areas tend to be grouped in clusters in Merton and Sutton CCGs. Merton, Mitcham, Wallington and Carshalton see the highest density of those from the most deprived quintile.

Figure 14: Overall deprivation quintiles for the study areas

Source: Mott MacDonald

Figure 15: Overall deprivation quantiles for the study area – higher density areas

Source: IMD 2015

2.12.2 A&E

Between 2008 and 2013, those living in the 10% most deprived Lower layer Super Output Areas (LSOA) of England made twice the number of attendances in A&E (in both minor and major departments) compared to those living in the 10% least deprived LSOAs.⁹⁰ The disproportionate use of A&E services by those from deprived communities has been explained by differences in need, the varying quality of alternative care in deprived areas and barriers to access.⁹¹

In addition, in 2015/16 A&E attendance rates were highest in the most deprived quintile. Children and young people from the most deprived areas experienced 58 per cent more A&E attendances than those in the least deprived areas (514.6 per 1,000 compared to 325.6 per 1,000).⁹²

Local stakeholders reported greater use of A&E by those people living in the deprived areas of the study area, relating this to lifestyle factors and delayed access to primary healthcare.

⁹⁰ NHS Digital (2013): 'Focus on Accident & Emergency'. Available at: <https://digital.nhs.uk/data-and-information/publications/statistical/focus-on/focus-on-accident-emergency-december-2013>

2.12.3 Acute medicine

It has been found that those living in the most socio-economically deprived quintile are more likely than those in the least deprived quintile to:

- have unplanned (8.2% v.4.1%) admission to hospital;
- or potentially preventable unplanned (1.7%v. 0.6%) admissions to hospital.⁹³

Working age adults from a deprived background are at greater risk of poorer health, low mental wellbeing, and respiratory problems, including asthma and breathlessness.⁹⁴ This may lead to the need to present at and disproportionately need acute services. Local stakeholders reported greater need for acute care for people living in in the deprived areas of the study area, relating this to lifestyle factors.

2.12.4 Emergency general surgery

Lifestyle factors such as smoking and obesity are identified as being particularly important in contributing to the need for emergency surgical services, and have well established links to deprivation.⁹⁵ These factors all lead to the development of conditions that require the need to use emergency general surgery for example diverticular disease, many cancers, vascular diseases, and many oesophageal and gastrointestinal conditions.⁹⁶

2.12.5 Obstetrics

There is evidence of a correlation between maternal obesity and socioeconomic deprivation. A large body of evidence links maternal obesity to adverse pregnancy outcomes, these include perinatal mortality (foetal deaths after 24 weeks of gestation and death before seven completed days), maternal death, cardiac disease, miscarriage or premature births, preeclampsia, gestational diabetes, and infections among other conditions.^{97 98} Maternal obesity is therefore likely to lead to a disproportionate need for obstetrics.

Further, the rate of maternal mortality has been found to be higher for those living in the most deprived areas.⁹⁹

2.12.6 Paediatrics

A variety of reasons cause children from poorer backgrounds to disproportionately need paediatric services. There is evidence to suggest that poverty and low income is a factor in driving poor health in children.¹⁰⁰ Children from deprived communities are more likely to have poor nutrition and live in poor quality housing. They are therefore more likely to suffer from poorer general health. Alongside this, there is evidence of disproportionate need in children from deprived communities for treatment for conditions such as speech problems, Attention

¹⁰⁰ Wickham, S. et al. (2016) 'Poverty and child health in the UK: using evidence for action'

Deficit Hyperactivity Disorder (ADHD), diabetes, asthma, sleep apnoea and cardiovascular diseases.¹⁰¹

There is also a strong correlation between teenage pregnancy and social deprivation. The rate of teenage pregnancy in girls under the age of 18 is almost five times higher in the most deprived areas compared to the least deprived.¹⁰² Babies of teenage mothers are at increased risk of some poor outcomes compared with babies of older mothers:

- 45% risk of infant death
- 30% less likely to breastfeed
- 30% higher risk of stillbirth
 - 20% higher risk of premature birth if a first baby
 - 90% higher risk of premature birth if a second baby
- 15% higher risk of low birthweight¹⁰³

3 Summary and next steps

3.1 Scoped in equality groups according to service area

There is evidence to suggest that the protected characteristic groups scoped in in chapter two have a disproportionate and differential need/use for the services under review (as shown below in Table 19. It is important to note that the report is not suggesting that other groups will not need the services which are under review, rather it is to suggest that there does not presently exist a body of evidence indicating a disproportionate or differential need/use.

Table 19: Scoped in equality groups according to services area

	A&E	Acute medicine	Emergency general surgery	Obstetrics	Paediatrics
Age – Children (those aged 16 and under) and younger people (those aged 16-24)	✓			✓	✓
Age – Older people (65 and over)	✓	✓	✓		
People with a disability	✓	✓		✓	✓
Gender re-assignment	✓				
Marriage and civil partnership					
Pregnancy and maternity		✓		✓	✓
Race and ethnicity	✓	✓		✓	✓
Religion and belief					
Sex	✓	✓	✓	✓	✓
Sexual orientation	✓				
Carers					
Deprivation	✓	✓	✓	✓	✓

Across all acute services disproportionate or differential needs/use were identified for protected characteristic groups. The only protected characteristic groups where there is currently no evidence to suggest a disproportionate/differential need or use are: marriage and civil partnership, religion and belief, and carers. While a disproportionate/differential need or use for acute service was not found for carers, the stakeholder interviews did highlight that carers will likely be impacted by changes to acute services as a result of changes to travel time and complexity when using acute services.

Although almost all protected characteristic groups were found to have a disproportionate or differential need/use for A&E services, generally, need for/use of acute services and the drivers for these varied between protected characteristic groups. However, within protected characteristics and across the different acute services some commonalities were found. In particular:

- Patients from deprived communities were found to have a higher than average need for/use of all acute services under review. There is a strong link between poverty and social inequality with poor physical and mental health. Certain lifestyle factors such smoking,

obesity and excess alcohol consumption, along with poor living and working conditions and limited access to healthy food, can all result in increased interaction with acute services.

- Patients from minority ethnic communities have a higher than average need for/use of all the services under review, apart from emergency general surgery. A key driver for need can often be tied with a higher deprivation prevalence amongst this group. However, there are also some health conditions which are also likely to be more salient amongst ethnic minority groups which can result in increased interaction with acute services. Further, stakeholder interviews suggested that this group tend to experience access issues with health services, particularly primary care, for reasons such as language barriers and cultural norms. Stakeholders indicated that this can result in a high use of acute services, such as A&E, as they are more likely to access services at a critical stage.
- Similar to ethnic minority communities, patients who have a disability also have a higher than average need/use for all the services under review, apart from emergency general surgery. Often disabled people require treatment as a result of, though not necessarily associated with, their disability (e.g. respiratory disease is the main cause of death in people with learning disabilities). As such, their disability can result in an increase use of acute services, particularly in cases what patients have multiple complex needs.
- When looking at differences by sex, need for acute services varies for males and females:
 - Females tend to have a high need for obstetrics, paediatrics, and emergency general surgery which tends to be linked to childbirth.
 - Males tend to have a high need for acute services such as A&E, acute medicine and emergency general surgery which tends to be driven by lifestyle factors, such as higher propensity than women to be involved in accidents and poor use of healthcare services. However, males are more likely to experience specific health issues which would bring them into contact which acute services such as congestive heart failure, long-term complication linked with diabetes and pneumonia.
- Finally, evidence suggests that older people tend to have a higher need for/use of emergency acute services such as: A&E, acute medicine and emergency general surgery. Generally, linked to age, this group experience a range of health concerns which would bring them into contact with acute services and which tend to be exacerbated by a high proportion of old people living longer with complex co-morbidities.

The demographic analysis found a number of geographical areas which have high densities of scoped in protected characteristic groups. In addition to this, it also looked at proportional representation of groups to understand where groups are particularly prevalent in a certain area (compared with the overall population composition in that area). The following table outlines the key findings:

Table 20: demographic analysis

Scoped in groups	Geographical areas in the primary study area a high proportion or density of these population groups, compared to the overall population
Age – Children (those aged 16 and under) and younger people (those aged 16-24)	<p>Density trends: The most concentrated density of those aged under 16 and those aged 16-24 are located within Merton and Sutton CCGs with the highest densities around Merton and Carshalton.</p> <p>Population trends: Across all three CCGs the proportion of children aged under 16 (20%) and people aged between 16 to 24 (9%) is broadly in line with the national average (19% and 11% respectively).</p>
Age – Older people (65 and over)	<p>Density trends: The highest densities of those aged 65 and largely clustered around Sutton and Merton CCG. In particular, Sutton CCG has a number of very high-density areas (over 2,000 per sq. km) located around St Helier and Sutton Hospitals</p> <p>Population trends: Across all three CCGs the overall proportion of those aged 65 and over (16%) is slightly lower than the national average (18%). However, Surrey Downs CCG has a high than average proportion of older of people (20%).</p>
People with a disability	<p>Density trends: The highest densities of people living with a disability are largely clustered around Sutton and Merton CCG. In both CCGs the density of people living with a disability tend to be highest in the areas located closest to a hospital (St George's, St Helier or Sutton).</p> <p>Population trends: The proportion of those with a disability (14%) across the three CCGs, is lower than the national average (18%).</p>
Gender re-assignment	No data available
Pregnancy and maternity	<p>Density trends: The densities of females aged 16-44 in both Sutton and Merton CCG with Sutton with the highest density clustered around Merton and nearest to St George's hospital</p> <p>Population trends: The proportion of women aged 16-44 (19%) is in line with the national average (19%). However, Surrey Down has a lower than the national average proportion of females aged 16-44 (16%) while Merton has slightly higher than average proportion (22%).</p>
Race and ethnicity	<p>Density trends: The highest density of BAME communities are concentrated in the north of the study area.</p> <p>Population trends: The proportion of those from BAME backgrounds is (30%) this is higher than the national average (20%). The proportion of BAME groups living within the three CCGs is very varied, over half of the population in Merton CCG is from a BAME background while Surrey Downs has below the national average (16%).</p>
Sex	In line with national averages
Sexual orientation	No data available
Deprivation	<p>Density trends: The most deprived areas tend to be grouped in clusters in Merton and Sutton CCGs. Merton, Mitcham, Wallington and Carshalton see the highest density of those from the most deprived quintile.</p> <p>Population trends: Sutton has the highest percentage</p>

3.2 Next steps

The findings of this research will be linked with a travel analysis being undertaken by Mott Macdonald.

The focus of this research highlights the key needs of protected characteristics within the study area. However, interviews with stakeholders invited discussion around the potential impact of any changes for those with a high need for acute services, as well as potential mitigations. When discussing the consolidation of acute services onto one site, the stakeholders highlighted the following:

- It was felt that the movement to one site will likely have positive benefits for all patients as it will mean that they have access to better facilities and more specialised staff. It is expected that there will be better staffing levels and communication between teams. As such, it was felt that safety and the quality of care for patients will improve.
- It was also felt that the consolidation of services would be an opportunity to design a system which is fit for purpose for patients. A number of stakeholders felt that when moving services attention should be given to how the service interacts with local community services. It was mentioned that the movement of acute services onto one site would risk losing some of the ties to patients' local communities providers. It was felt therefore, that work needs to be done to build strong communication channels and improve technology to support new information sharing.
- As well as links to community providers, concern was expressed across the majority of stakeholders around the difficulty of travelling to the site. It was felt that wherever the site is located (Epsom, St Helier or Sutton) some patient groups would struggle to travel there. It was suggested by stakeholders that difficulties linked to travelling to the site were most likely to negatively impact vulnerable groups. In particular, it was often suggested that older people, those with a mental health condition, those with a learning disability, those with a physical disability and those from deprived communities may experience difficulty with traveling, especially when using public transport.
- To mitigate difficulties with travelling, a number of stakeholders suggested that it would be important for the commissioners to work with local transport providers to discuss improving access to the chosen site across the three CCGs. Consideration would also need to be given to parking costs to make travelling there more appealing.
- Stakeholders further suggested that it would be important to undertake a strong public awareness campaign to ensure that patients are clear around how to access and use acute services. It was felt that the Trust would need to be very clear with patients around the quality and safety benefits of consolidating service to prevent inappropriate use of other services and to prevent patients going to other sites.

The findings above outline initial thoughts around the potential impact of any change in the provision of acute services. It is recommended that the local CCGs takes these findings further through undertaking a full Equality Impact Assessment. This assessment would involve further stakeholder engagement (particularly with community groups), a full appraisal of the potential positive and negative impacts which could result from any changes to acute services. It would also explore potential mitigation actions which could be taken, as well as reviewing where enhancements can be made to ensure realisation of positive impacts.
